# Secure Colour Image Encryption Based on Dynamic DNA Coding and Different Chaotic Maps 

Subhajit Das ${ }^{* 1}$, Manas Kumar Sanyal ${ }^{2}$, and Joyjit Mandal ${ }^{3}$<br>${ }^{* 1}$ University of Kalyani, Department of Business Administration, Kalyani, India, subhajit.batom@gmail.com ${ }^{2}$ University of Kalyani, Department of Business Administration, Kalyani, India, manas_sanyal@rediffmail.com ${ }^{3}$ Central University of Rajasthan, Department of Computer Science, Ajmer, India, joyjitmandal1 @ gmail.com

#### Abstract

In recent years several chaos-based encryptions have been developed due to its extraordinary property, but its debris is an inexorable discrepancy for developing efficiency and security. In this paper, a new colour image encryption and decryption scheme with different dimensional chaos functions has been used. Onedimensional logistic map, two-dimensional Sine-Henon alteration map, and three-dimensional Lorenz chaotic systems have been applied in different stages of the encryption model. Moreover, to protect from different types of attacks, dynamic DNA sequences with its reversible operations have been applied. Different experimental outcomes exhibit the effectiveness and efficiency of the proposed method. It is also proved that the proposed method can combat statistical attack, differential attack and exhaustive attack.

Index Terms: DNA operation, dynamic DNA sequence, image encryption, Lorenz chaotic system, SHA 256, Sine-Henon alteration

## I. Introduction

This In the age of globalization, fast and secure communication brings a revolutionary change in human society. There are so many free applications in the market through which people can easily communicate with each other. Nowadays people are very much interested in multimedia communication services i.e. picture, voice, video rather than text message communication. As a result, confidentiality and security are a great issue for this type of communication. The digital image is an extensive information repository of communication. So preserving this information from unauthorized access during transmission is very much necessary. Traditional block ciphers such as Triple-DES, AES, and IDEA are not convenient for image cryptology. This is because the security of these algorithms is mainly concentrated on high
computational cost whereas images are characterized by huge data capacity and high correlation between their neighbour pixels. Finding an efficient, effective, and secure image encryption algorithm has become a universal concern for researchers. Researchers applied different types of mathematical and statistical tools like the elliptic curve [Laiphrakpam Dolendro Singh (2015) et al.], fractional wavelet transform [Linfei Chen (2005) et al.], reversible cellular automata [Jun Jin (2012) et al.], image filtering [Xinsheng Li (2019) et al.], and pixel adaptive diffusion to overcome the challenge. Among them, a chaos-based image cryptosystem contributes an optimal establishment between security and efficiency. The quality of the image encryption algorithm is very enriched by dynamic properties of a chaotic system. Chaos-based image encryption algorithm performed in two stages: one is pixel position changing and the other is pixel value changing. In pixel position changing, the arrangement of pixels is changed and a new scrambled image is created. But the pixel position changing stage leads to the histogram of the image is the same as the original image. As a result, evolution of security is not accurately managed. On the other hand, in the pixel value changing method values are changed by using chaotic sequence and provide higher security but in terms of encryption effect this method is not good enough [Qiang Zhang (2012) et al.]. Most of the low dimensional chaos-based encryption model is confined by the computer word length which causes deterioration in the chaotic dynamics [Y. H. Zhang (2015) et al.]. There is no apprehension about that single chaotic map-based image encryption technique cannot support the surveillance of the encrypted image [Ying Niu (2017) et al.].

To overcome the drawback of single dimensional chaotic map

[^0]in encryption Hua et al [Zhongyun Hua (2015) et al.] introduced a new two-dimensional sine logistic modulation map (2DSLMM). They proved this map has larger chaotic range, many parameters, and good enough chaotic property. Authors [Hayder Natiq (2018) et al.] applied another two-dimensional chaotic map that is Sine-Henon alteration map in image encryption. SineHenon 2D alteration map is developed from Henon and Sine maps. Using dynamical analysis and simple entropy algorithm authors proved that 2D SHAM is overall hyperchaotic with high complexity. Moreover, Niu et al proposed a new threedimensional Lornez chaotic system [Ying Niu (2017) et al.] with the DNA sequence. They described that Lorenz's chaotic system generates a more complex system structure that can develop a combination of univariate or multivariate chaotic sequences. Besides the hyperchaotic system, DNA coding system materialize an insurgent change in image cryptology. DNA coding system import some exceptional features such as huge storage, massive parallelism and ultra-power consumption. Moreover, DNA coding based logical operation is truly reversible in nature that is very crucial for image cryptology [QiangZhang (2010) et al.][ R. Guesmi (2016) et al.][Changjiang Zhu (2020) et al.][ Xiuli Chai (2019) et al.]. But our main focus is on the colour image encryption technique. The structure of colour image is different from the greyscale image because the colour image consists of three different channels namely Red, Green, and Blue. Two logistic maps and DNA sequence operation-based image encryption was proposed by Zhang et al but their proposed method has failed to get the desired encryption quality due to the low randomness of the applied logistic maps. In ref [L. Li (2011) et al.] authors applied Arnold map before DNA coding but their applied key value was independent of the plain image. So, this method cannot resist against different text attacks. Wang et al [ Wang (2018) et al.] proposed a Lorenz system based colour image encryption where DNA permutation and logical operations can break the bit planes of the input image completely.

Analysing these characteristics, we propose an exclusive colour image encryption based on different chaotic maps and dynamic DNA sequences. The specialty of our proposed system is that it uses an extremely high order key value using SHA 256 that depends on the plain image. Moreover, three different channels of the colour image are related thoroughly throughout the encryption process. The proposed method is a combination of bit-level shuffling and pixel shuffling and the encryption process is based on dynamic DNA coding and reversible DNA sequence operations. The paper demonstrates as section 2 describes basic tools applied in our method, sec 3 demonstrate the encryption process including key generation, bit shuffling and pixel shuffling. In section 4 decryption processed is discussed. The experimental outcomes are reported in section 5 and lastly paper is closed with a conclusion.

## II. Basic Theory

## A. One Dimensional Logistic Map

In our proposed method one dimensional logistic map has been used to generate two random sequence numbers. These two random sequences are used to select a particular DNA coding rule and a particular DNA operation type. Both operations are used for encryption stage. The one-dimensional logistic map has been defined by

$$
\begin{equation*}
x_{n+1}=\alpha x_{n}\left(1-x_{n}\right) \tag{1}
\end{equation*}
$$

Where $x_{n} \in(0,1), \alpha \in(0,4)$. In this equation value of $\alpha$ and value of $x$ will be the input. It already proved that the system is in chaotic state when $3.99 \leq \mu \leq 4$.
B. Two Dimensional Logistic Map (2D Sine-Henon alteration map)
In our proposed algorithm 2D Sine Henon alteration map has been used to generate two extremely different random alterations. This type of 2D map is derived from Henon and Sine map. First Henon map is modulated and result is used to enhance the nonlinearity and randomness of sine map. The new 2D SHAM is defined by

$$
\begin{align*}
& x_{1}(n+1)=\left(\frac{1}{n b}\right) \sin \left(1+a x_{1}(n)^{2}-\pi^{2} x_{2}(n)\right)  \tag{2}\\
& x_{2}(n+1)=\left(\frac{2}{n b}\right) \sin \left(\pi b x_{1}(n)\right) \tag{3}
\end{align*}
$$

Here the value of a and b are known as controlled parameters. Where $0 \leq a \leq 5 \quad$ and $\quad 0.45 \leq b \leq 2$. Natiq et al(2018)showed the basic dynamic properties, Jacobian eigenvalues, trajectory, Bifurcation diagram, LE and sensitivity dependence test. Authors proved that 2D-SHAM is overall hyper chaotic and high sensitive to its beginning value and control parameter.

## C. Lornez Chaotic Systems

In 1963, Edward Lorenz, with the help of Ellen Fetter, invented a very easy simplified mathematical 1 model for atmospheric convection. It is a system that consists of three ordinary differential equations. These equations are known as Lorenz equations [Xinsheng et al(2019)]. From a technical standpoint, the Lorenz system is nonlinear, non-periodic, three-dimensional and deterministic. These three dimensions are used to generate three different matrices. These three matrices are used as a different keyword for three different channels of original image. It is very much essential to disperse the system by the fourth order Runge-Kutta method for very sensible random number generation. 3D chaotic system is defined by

$$
\begin{align*}
x^{\prime} & =a(y-x)  \tag{4}\\
y^{\prime} & =c x-y-x z  \tag{5}\\
z^{\prime} & =x y-b z \tag{6}
\end{align*}
$$

Here $a, b, c$ are system parameters. Initial values of $x, y, z$ will be computed or taken as a key word. The Lorenz Chaotic system in chaotic state when $\mathrm{a}=10, \mathrm{~b}=8 / 3$ and $\mathrm{c}=28$.

## D. DNA Sequence Rule

A DNA sequence has four different types of nucleotides they
are Adenine(A), Thymine(T), Guanine(G) and Cytosine(C). Here ' $A$ ' can pair with ' $T$ ' and ' $G$ ' can pair with ' $C$ '. In other words, it can be said A, T and G, C are in complementary relation. Four DNA nucleotides are represented by two bits binary sequences. They are $00,01,10,11$. As per the binary complementary rule, complement of 0 is 1 and vice versa. So, following this rule, 00 and 11 are a complement to each other. Similarly, 01 and 10 are also complementary to each other. Out of four sequences i.e. $00,01,10,11$ anyone can choose any sequence to serve a nucleotide keeping DNA complementary rule in mind. Following this way there possibly 4 ! i.e. 24 types of combination for DNA coding. Scrutinizing the complementary concern [Chai XL et al(2019)] there are eight kind of valid rules that are given in table 1 . In our proposed method pixel values are changed to a DNA sequence using a specified rule no. For example, if the value is 225 , its equivalent binary sequence is ' 11100001 ', which can be coded as 'TGAC' according to rule no 1 and coded as 'GTCA' according to rule no 3.

Table I. DNA coding rules

| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $00-\mathrm{A}$ | $00-\mathrm{A}$ | $00-\mathrm{C}$ | $00-\mathrm{C}$ | $00-\mathrm{G}$ | $00-\mathrm{G}$ | $00-\mathrm{T}$ | $00-\mathrm{T}$ |
| $01-\mathrm{C}$ | $01-\mathrm{G}$ | $01-\mathrm{A}$ | $01-\mathrm{T}$ | $01-\mathrm{A}$ | $01-\mathrm{T}$ | $01-\mathrm{C}$ | $01-\mathrm{G}$ |
| $10-\mathrm{G}$ | $10-\mathrm{C}$ | $10-\mathrm{T}$ | $10-\mathrm{A}$ | $10-\mathrm{T}$ | $10-\mathrm{A}$ | $10-\mathrm{G}$ | $10-\mathrm{C}$ |
| $11-\mathrm{T}$ | $11-\mathrm{T}$ | $11-\mathrm{G}$ | $11-\mathrm{G}$ | $11-\mathrm{C}$ | $11-\mathrm{C}$ | $11-\mathrm{A}$ | $11-\mathrm{A}$ |

## E. DNA Operations

By using DNA sequence, it is possible to perform some algebraic operations [101,102,103,104]. They are most common logical operation-addition, subtraction, XOR and XNOR. The

Table II. XOR operation

| XOR | A | C | T | G |
| :--- | :---: | :---: | :---: | :---: |
| A | A | C | T | G |
| T | T | G | A | C |
| C | C | A | G | T |
| G | G | T | C | A |

Table IV. ADDITION

| + |  | C | T | G |
| :---: | :---: | :---: | :---: | :---: |
| A | C | A | G | T |
| T | G | T | C | A |
| C | A | C | T | G |
| G | T | G | A | C |

Table III. XNOR operation

| XNOR | A | C | T | G |
| :--- | :---: | :---: | :---: | :---: |
| A | C | A | G | T |
| T | T | G | C | A |
| C | A | C | T | G |
| G | T | G | A | C |

Table V. SUBSTRACTION

| + |  | C | T | G |
| :---: | :---: | :---: | :---: | :---: |
| A | C | A | G | T |
| T | G | T | C | A |
| C | A | C | T | G |
| G | T | G | A | C |

influences of these DNA operations are that they are truly reversible in nature. Addition and subtraction are reversable each other, XOR and XNOR are themselves reversable in nature. This is the most important useful property in image encryption. Table [2-4] serve the result of each DNA operations considering that nucleotides are coded according to rule no 7 in Table I.

## III. Proposed Algorithm

Fig 1 represents the total encryption process of our proposed algorithm. Our encryption process made up with four sub steps key generation, Partition of image, bit shifting, pixel shuffling, construction of corelating matrix, encryption and decryption.

## A. Key Generation Algorithm

To produce a unique secret key SHA-256 has been used in our proposed algorithm. SHA -256 is used by many cryptographic algorithms because slight change in input value produces completely different output value. First of all we have produced a hex value using KeyGen() function. In this function a simple calculation has been performed using the values of Red, Green, Blue channel of colour image and an arbitrary number. The outcome of KeyGen() has been applied to SHA-256 to produce unique 256 bit hash value. This hash value has been used to initialize different input parameters for encrypting the colour image. As the key value totally depends on input image, so our algorithm can resist against known plain text, chosen cipher text and chosen plain text attacks.

## KeyGen()

Input: Input Image and four-bit decimal random number.
Output: a 256-bit long key value

1. Devide the colour image consists of $m$ rows and $n$ columns into Red Channel(R), Green Channel(G) and Blue channel(B). Now we have three different matrices ( $\mathrm{R}, \mathrm{G}, \mathrm{B}$ ) of size $m$ by n .
2. $R_{1=} \operatorname{celing}\left(\frac{\sum_{i=1}^{m} \sum_{j=1}^{n} R_{i, j}}{m \times n}\right), \quad G_{1=} \operatorname{celing}\left(\frac{\sum_{i=1}^{m} \sum_{j=1}^{n} G_{i, j}}{m \times n}\right)$, $B_{1}=\operatorname{celing}\left(\frac{\sum_{i=1}^{m} \sum_{j=1}^{n} B_{i, j}}{m \times n}\right)$
3. key $_{\text {val }}=\left(\left(\left(\left(\left(R_{1} \times 10^{3}\right)+G_{1}\right) \times 10^{3}\right)+B_{1}\right) \times 10^{3}\right)+$ randbetween $(1-1000)$
4. key $=$ SHA256 $\left(\right.$ key $\left._{\text {val }}\right)=\left\{k_{1}, k_{2}, k_{3}, \ldots \ldots . k_{64}\right\}$ Each K contain 4 hexadecimal bit.
5. $M=$ rem $\left(h e x \_d e c i m a l\left(k_{1}\right), 8\right)$.
6. $N=$ rem $\left(\right.$ hex_decimal $\left.\left(k_{2} k_{3}\right), 99\right)+1$
7. $X_{0}=\left(\right.$ hex_decimal $\left.\left(k_{4} k_{5} k_{6} k_{7} k_{8} k_{9} k_{10} k_{11}\right) \times 10^{-9}\right)$
8. $Y_{0}=\left(\right.$ hex_decimal $\left.\left(k_{12} k_{13} k_{14} k_{15} k_{16} k_{17} k_{18} k_{19}\right) \times 10^{-9}\right)$
9. $a=\operatorname{rem}\left(\right.$ hex_decimal $\left.\left(k_{20} k_{21} k_{22} k_{23}\right), 5\right)$
10. $b=0.45+$ rem (hex_decimal $\left(k_{24} k_{25} k_{26} k_{27}\right), 2$
11. $X_{1}=\left(\right.$ hex $\left._{\text {decimal }}\left(k_{28} k_{29} k_{30} k_{31} k_{32} k_{33} k_{34} k_{35}\right) \times 10^{-9}\right)$
12. $Y_{1}=\left(\right.$ hex $\left.x_{\text {decimal }}\left(k_{36} k_{37} k_{38} k_{39} k_{40} k_{41} k_{42} k_{43}\right) \times 10^{-9}\right)$
13. $Z_{1}=\left(\right.$ hex_decimal $\left.\left(k_{44} k_{45} k_{46} k_{47} k_{48} k_{49} k_{51}\right) \times 10^{-9}\right)$
14. $X_{2}=\left(\right.$ hex $\left._{\text {decimal }}\left(k_{52} k_{53} k_{54} k_{55} k_{56} k_{57} k_{58} k_{59}\right) \times 10^{-9}\right)$
15. $\propto=3.99+\left(\right.$ hex_decimal $\left.\left(k_{60} k_{61} k_{62} k_{63} k_{64}\right) \times 10^{-5}\right)$

Here celing $(n)$ function gives the nearest highest integer value of n . randbetween(range) function generates a random number within the specified range $\cdot \operatorname{rem}(a, n)$ generates remainder part by dividing a by n. hex_decimal( $n$ ) converts hexadecimal number n to its equivalent decimal number. SHA256(a) produces 256 bit long hash value on input
value a .

## B. Partition of Image

we describe two functions add() and division() that are most useful for our encryption.
i) add () that performs concatenation of matrices of same order side by side in column direction. It converts $m \times n \times 3$ matrix into $m \times 3 n$
ii)division () that breaks a matrix into three equal matrices in column direction i.e it converts $m \times 3 n$ matrix into three matrix of $\mathrm{m} \times \mathrm{n}$.

Let the original colour image $I M$ of size $m$ rows and $n$ columns.

$$
I M=|I M|_{m \times n \times 3}
$$

Three different channels of input colour image (red channel, green channel and blue channel) are separated and stored one by one in column direction.

$$
\begin{gather*}
I M_{m \times n \times 3}=\left(I M_{m \times n}^{R}, I M_{m \times n}^{G}, I M_{m \times n}^{B}\right) \\
I M 1_{m \times 3 n}=\operatorname{add}\left(I M_{m \times n}^{R}, I M_{m \times n}^{G}, I M_{m \times n}^{B}\right) \tag{10}
\end{gather*}
$$

## C. Bit Shifting

To make our proposed algorithm dependent upon plain image a circular shift operation ShiftCircu() is introduced. This function first circularly shift $M$ number of bits of pixel resides in the upper left corner of the plain image. Then depending upon its new value, the other neighbour pixel values are updated. The value of M is constant provided by key value. ReShiftCircu() function is reverse of ShiftCircu() function.

Input: - IM1 and M
Output- A m $\times 3 n$ matrix IM2.

## ShiftCircu()

1. value $=$ M;
2. for $i=1$ to $m$
3. for $j=1$ to $n$
4. new_image $(i, j)=$ circularshift $($ image $(i, j)$, ,value $)$
5. value $=$ rem(new_image $(i, j), 7)+1$
6. end of inner for in step 2
7. end of outter for in step 1
8. end

Here circularshift ( $\mathrm{a}, \mathrm{n}$ ) shifted n number of bits circularly on a and rem $(a, n)$ operation generates the remainder part if a is divided by $n$.

$$
I M 2=\operatorname{ShiftCircu}(I M 1, M)
$$

```
ReShiftCircu()
    1. val=0;
    2. for }i=1\mathrm{ to }
    3. for j=1 to n
    4. new_image(i,j)=circularshift(image(i,j),value)
    5. value }=8-(\operatorname{mod}(\mathrm{ new_image (i,j),7) +1)
    6. end of inner for in step 2
    7. end of outter for in step 1
    8. new_image(1,1)=circularshift(image(i,j),(8-M))
    9. end
```

## D. Pixel Shuffling

In our proposed algorithm 2D Sine Henon Alteration Map is
used to generate two extremely random numbers that used for pixel shuffling. Using equation 1 and 2 random sequences are generated. These sequences are used to change the locations of each pixel's row wise and column wise. Pixel shuffling using two random sequences ( $\boldsymbol{S h u f f}()$ ) is described below. We introduce another function $\boldsymbol{R e}$ _Shuff() that arranges the pixels into its original position.This function is used during decryption process.

## Shuff()

1. To avoid harmful effect of transactional procedure we iterate 2D SHAM equations N0 times. Here N0 is a fixed number.
2. Generate two sequences (Ic and $I r$ ) each consist of $3 \mathrm{~m} * \mathrm{n}$ numbers with initial conditions ( $x_{0}, y_{0}, a, b$ )
3. $I_{c}$ divided into $3 n$ equal parts where each part contains $m$ elements and $\operatorname{Ir}$ devided into $m$ equal parts where each part contains $3 n$ elements.
4. Every part from Ic are shorted into ascending order and every parts of Ir are sorted into descending order.

$$
\begin{equation*}
I_{c}=\left\{C_{i}\right\}: 1 \leq i \leq 3 n ; C_{i}=\operatorname{aesc}\left(x_{1}, x_{2} \ldots . x_{m}\right) \tag{11}
\end{equation*}
$$

$\left.I_{r}=\left\{R_{j}\right\}: 1 \leq j \leq m ; \quad R_{j}=\operatorname{desc}\left(x_{1}, x_{2}, \ldots \ldots, x_{3 m}\right)\right\}:$
5. After sorting we keep locations of replacement of each element and change the pixel position accordingly. For shuffling each column location change of each $C_{i}$ and shuffling each row location change of each $R_{j}$ is considered. Process of location changing of pixels is described below with an example.

## Example:

let consider a vector of (v) of eight elements $v=$ $\{102,202,56,78,87,97,100,187\}$ a random sequence be $\quad r=\{58.2,100.5,23.4,4.3,89.6,35.4,23.6,17.2\}$.
$r 1=\operatorname{aesc}(r)=\{4.3,17.2,23.4,23.6,35.4,58.2,89.6,100.5\}$
Hence the location tracker defined as $L C=\{4,8,3,7,6,1,5,2\}$
According to LC, vector V is assembled as $v^{\prime}=\{97,187,56,102,100,87,78,202\}$
After sorting r it is observed that $4^{\text {th }}$ element moves in first position, 8th element moves into $2^{\text {nd }}$ position and so on. To assemble any vector using this location tracker we moves first element to forth location. Second element to $8^{\text {th }}$ location, $3^{\text {rd }}$ element to $3^{\text {rd }}$ location, $4^{\text {th }}$ element $7^{\text {th }}$ location and so.

## Re_shuff()

To get back original v to perform Re_Shuff() where v' and LC taken as input. In this method forth element of $V$ ' moves in first position, $8^{\text {th }}$ element moves onto second position, $3^{\text {rd }}$ element moves in $3^{\text {rd }}$ position and so on.

Shuff() method is used during encryption process and Re_shuff() method is used in decryption process.
after sorting it is observed that in vector ' $r$ ' element 58.2 of fist position is shifted into $6^{\text {th }}$ position and element in $2^{\text {nd }}$ position (100.5) shifted into $8^{\text {th }}$ position. Considering this way the location tracker(LC) defined as $L C=\{4,8,3,7,6,1,5,2\}$. Following the location tracker the final output of $\operatorname{shuff}()$ on vector $v$ is $v=\{78,187,56,100,97,102,87,202\}$

After shuffling matrix IM3 is obtained

$$
I M 3=\operatorname{shuff}\left(I M 2, I_{c}, I_{r}\right)
$$

## E. Construction of Correlating Matrix

Lorenz chaotic system is applied here for generating three different correlating matrices. These correlating matrices are generated by solving equations by RK method (order 4). Like other chaotic equations these equations are also preliterate system $\mathrm{N}_{0}$ times for avoiding the harmful effects. Forth order RK method solution is given by

$$
\begin{align*}
x_{n+1} & =x_{n}+\frac{h}{6}\left(K_{1}+2 K_{2}+2 K_{3}+K_{4}\right)  \tag{13}\\
y_{n+1} & =y_{n}+\frac{h}{6}\left(L_{1}+2 L_{2}+2 L_{3}+L_{4}\right)  \tag{14}\\
Z_{n+1} & =Z_{n}+\frac{h}{6}\left(M_{1}+2 M_{2}+2 M_{3}+M_{4}\right) \tag{15}
\end{align*}
$$

Where
$K_{j}=a\left(y_{n}-x_{n}\right)$
$L_{j}=c x_{n}-y_{n}-x_{n} z_{n}$
$M_{j}=x_{n} z_{n}-b z_{n}$
From equation (13), (14) and (15) we generate $m * n$ numbers from each equation. With initial values $\left(x_{1}, y_{1}, z_{1}\right)$ From these sequences three $m$ by $n$ matrix is constructed $\left(\operatorname{cor}^{x}\right),\left(\operatorname{cor}^{y}\right),\left(\operatorname{cor}^{z}\right)$

$$
\begin{equation*}
\text { Co_mat }=\operatorname{add}\left(\operatorname{cor}_{m \times n}^{x}, \operatorname{cor}_{m \times n}^{y}, \operatorname{cor}_{m \times n}^{z}\right) \tag{16}
\end{equation*}
$$

F. Encryption

Input:IM3, Co_mat, $x_{2}, \alpha$
Output: Encrypted image (EI)
At this point we apply divide division function on IM3 that breaks the matrix into three equal parts. From one-dimension logistic map described in equation (1) with initial value $\left(x_{2}, \alpha\right)$,two sequences $P$ and $Q$ are computed.

$$
\begin{gather*}
P=\left\{p_{1}, p_{2}, p_{3}, \ldots \ldots \ldots ., p_{m \times n \times 3}\right\}  \tag{17}\\
Q=\left\{q_{1}, q_{2}, q_{3}, \ldots \ldots \ldots, q_{m \times n \times 3}\right\}  \tag{18}\\
P^{\prime}=\left\{\bmod \left(\left(p_{i} \times 10^{4}\right), 7\right)+1\right\}: \mathrm{i}=1,2, \ldots m \times n \times 3 \\
Q^{\prime}=\left\{\bmod \left(\left(q_{i} \times 10^{4}\right), 3\right)+1\right\}: \mathrm{i}=1,2, \ldots m \times n \times 3
\end{gather*}
$$

of DNA encoding operation which are present in Table no 1. Numbers from $Q^{\prime}$ represents DNA operational code. In our method code 1 indicates for addition, code 2 indicates for subtraction, code 3 indicates XOR and code 4 indicates XNOR. Encryption method is described below.

```
Encry()
    Input: p', q',Co_mat,IM3
    Output: Encrypted dimge
    1.set count=0;
    2.for i=1 to m
    2.for j=1 to 3n
    3.c=to_DNA(Co_mat(i,j),p'(count));
    4.d=to_DNA(IM3(i,j),p'(count));
    5.EI(i,j)=from_DNA(DNA_op(c,d,q'(count)), p'(count));
    6.End if j
    7.End of i
    8.count=count+1;
```

## 9.end

Here to_DNA(a,n) converts the decimal value into DNA sequence according to rule no $n$. from_DNA(a,n) converts DNA sequence a into ints equvalent decimal number following rule no n.DNA_op(c,d,n) performs one of DNA algebraic operation specified by $n$ between c and d. At this point EI is encrypted image. Apply division to EI to get three equivalent matrix and using this matrix a three-dimensional image is constructed.

$$
\begin{aligned}
& E I^{1}, E I^{2}, E I^{3}=\text { division }(E I) \\
& \text { Encrypted }_{\text {image }}=m \times n \times 3
\end{aligned}
$$

where $m$ and $n$ are horizontal and vertical magnitude of image.

## G. Decryption

Our proposed method is symmetric key encryption means same key is used for encryption as well as decryption. At the receiver end from the key value $P^{\prime}, Q^{\prime}$ is generated from one dimension logistic map, $\left(\operatorname{cor}^{x}\right),\left(\operatorname{cor}^{y}\right),\left(\operatorname{cor}^{z}\right)$ is generated from three dimension Lorenz chaotic sequence and $I_{c}, I_{r}$ generated from 2D SHAM chaotic map.

Step 1: apply division to encrypted image for getting three different two dimensional matrix.

$$
\left\{D I^{1}, D I^{2}, D I^{3}\right\}=\text { division }(E I)
$$

Step 2: apply $\boldsymbol{a d d}()$ to EI .

$$
D I 1=\operatorname{add}\left(D I^{1}, D I^{2}, D I^{3}\right)
$$

Step 3: Before apply Encry() a little change have been made in sequence $Q^{\prime}$.As addition and subtraction operation of DNA coding are reversable each other so in sequence $Q^{\prime}$ value 1 is converted to 2,2 is converted to 1 and value 3 and 4 are remain unchanged. At this point a new sequence $Q^{\prime \prime}$ is obtained.

$$
D I 2=\operatorname{Encry}\left(D I 1, C o_{m a t}, p^{\prime}, Q^{\prime \prime}\right)
$$

```
Step 4: apply Re_shuff()
                        DI3 = Re_shuff (DI2, I},\mp@subsup{I}{c}{},\mp@subsup{I}{r}{}
```

Step 5. Apply ReShiftCircu(). input -DI3 and M output- Decrypted Image(DI)

1. val=0;
2. for $i=1$ to $m$
3. for $j=1$ to $n$
4. new_image $(i, j)=$ circularshift $($ image $(i, j)$, value $)$
5. value $=8-(\bmod ($ new_image $(i, j), 7)+1)$
6. end of inner for in step 2
7. end of outter for in step 1
8. new_image( 1,1 )=circularshift(image $(i, j),(8-M))$
9. end

$$
D I=\operatorname{ReShiftCircu}(D I 3, M)
$$

step 6. apply division () to $D I$

$$
\left\{D I_{1}, D I_{2}, D I_{3}\right\}=\operatorname{division}(D I)
$$

Constructing these three matrix final Decrypted image is obtained.

$$
\text { Decrypted }_{\text {image }}=m \times n \times 3
$$

Fig. 1. Block diagram of proposed image encryption approach

## IV. Performance Analysis

Efficiency of our proposed algorithm is tested by using colour benchmark images Babun, Lena, Papers, Flower of size $256 \times 256$. As the keyword of our method depends upon input image so to encrypt these images, we applied appropriate keyword for each image. Visual Analysis of described method demonstrate in Fig 2. Test case images are shown in Fig 2(a), their corresponding encrypted image are shown in 2(b) and in Fig 2(c) images after decryption are shown. It has been shown that images of 2(a) and 2(c) similar.

Fig. 2. a) input image, b)encrypted image, c)decrypted image

## A. Key Sensitivity

To analyse the key sensitivity of our proposed algorithm we change a single bit of the key value and applied in Lena imge. Fig 3a and Fig 3b show two encrypted images with a single bit change in their key value. The differences between the two encrypted images are shown in Fig 3c. It has been observed that we have obtained a completely different cipher image. Both analyses and simulations demonstrate that the proposed algorithm is key sensitive and a slight change in the key value will cause a momentous variation on the output.

Fig. 3.a) Encrypted Lena, b) Encrypted Lena with single bit change, c) Difference a and c

## B. Histogram Analysis

An image encryption algorithm is said to be perfect if it produces a constant distribution of pixels for encrypted images. Fig $4 \mathrm{a}, 4 \mathrm{~b}, 4 \mathrm{c}, 4 \mathrm{~d}$ show the histograms of four different cipher images. From these figures, we conclude that our model produces constant distributed histograms for different encrypted images and it is almost impractical for an adversary to extract any kind of important information from the histogram of cipher image.

| Image | Histogram of Original Image | Histogram of encrypted Image |
| :---: | :---: | :---: |
| Babun |  |  |
| Lena |  |  |
| Pappers |  | RGB image histocran $\square$ |

Fig. 4. Different histogram of original and encrypted image

## C. Different Attack

UACI (Unified Average Changing Intensity) and NPCR (Number of Pixel Change Rate) are widely used to check the resistance against different attack of proposed encryption algorithm. UACI and NPCR can be defined as

$$
\begin{gathered}
U A C I=\frac{1}{X \times Y}\left[\sum_{i, j} \frac{\left|C_{1}(i, j)-C_{2}(i, j)\right|}{255}\right] \times 100 \% \\
D_{(i, j)}=\left\{\begin{array}{cc}
1, & C_{p}(i, j) \neq C_{e}(i, j) \\
0 & \text { otherwise }
\end{array}\right.
\end{gathered}
$$

$$
\begin{equation*}
N P C R=\frac{\sum_{i, j} D(i, j)}{X \times Y} \times 100 \% \tag{22}
\end{equation*}
$$

Where C 1 and C 2 are two different encrypted images in which their input images have randomly selected only one pixel difference from each other. X and $Y$ are the height and width of
input image. Table VI demonstrate the computed UACI and NPCR values of our proposed algorithm. Considering two random images, the maximum expected value of UACI is $33.5 \%$ and maximum expected value of NPCR is $99.63 \%$ [Kwok et $\mathrm{al}(2017)]$. Analysing the values of table 1 it concluded that values are close to the ideal one.

Table VI. NPCR and UACI values of different color image

| images | UACI | NPCR |
| :---: | :---: | :---: |
| Babun | 33.4878 | 99.6345 |
| Lena | 33.4716 | 99.6132 |
| Pappers | 33.4538 | 99.5906 |
| Flower | 33.5019 | 99.5816 |
| Fireworks | 33.5871 | 99.5785 |
| Hill | 33.4787 | 99.5547 |
| Monalisa | 33.5146 | 99.6015 |
| leaves | 33.5648 | 99.5974 |

## D. Correlation Analysis

An encryption algorithm is said to be good if it significantly reduces the correlation between adjacent pixels of the ciphered images. To calculate the correlation of plain text image and cipher text image we first select randomly 2500 pairs of two adjacent pixels from an image. Then the correlation coefficients of adjacent pixels in horizontal, vertical and diagonal directions are computed using equation $23,24,25,26$.

$$
\begin{align*}
& r_{x y}=\frac{\operatorname{cov}(x, y)}{\sqrt{D(x)} \sqrt{D(y)}}  \tag{23}\\
& E(x)=\frac{1}{S} \sum_{i=1}^{S} x_{i}  \tag{24}\\
& D(x)=\frac{1}{S-1} \sum_{i=1}^{S}\left(x_{i}-E(x)\right)^{2} \tag{25}
\end{align*}
$$

$$
\begin{equation*}
\operatorname{cov}(x, y)=\frac{1}{S} \sum_{i=1}^{S}\left(x_{i}-E(x)\right)\left(y_{i}-E(y)\right) \tag{26}
\end{equation*}
$$

$x$ and $y$ are two adjacent pixels in the image. $S$ represents total number of duplets(x,y) obtained from the image. Table VII demonstrate the correlation coefficient of test images.

Table VII. Correlation coefficient of different colour image

## E. Information Entropy Analysis

An arbitrary distribution of media file is measured using information entropy. Information entropy is calculated using the formula described below[12].

$$
\begin{equation*}
H(m)=\sum_{i=0}^{2^{n}-1} p\left(m_{i}\right) \log _{2} \frac{1}{p\left(m_{i}\right)} \tag{27}
\end{equation*}
$$

The entropy value for an encrypted image should be as high as possible, and for ideal situation it is very closer to 8 [Ying et al (2017)]. The result of computed entropy value of our proposed algorithm have been furnished in table 8. Entropy values of encrypted image demonstrate that our proposed techniques are
quite secure in the face of entropy attacks. Presented in Table VIII
Table VIII. Information Entropy of different images

| Image | Channel 1 | Channel 2 | Channel3 |
| :--- | :--- | :--- | :--- |
| Lena | 7.99789 | 7.99827 | 7.99880 |
| Babun | 7.99726 | 7.99667 | 7.99720 |
| Pappers | 7.99749 | 7.99734 | 7.99745 |
| Flower | 7.99762 | 7.99703 | 7.99757 |
| Fireworks | 7.99798 | 7.99819 | 7.99787 |
| Hill | 7.99816 | 7.99750 | 7.99788 |
| Monalisa | 7.99716 | 7.99756 | 7.99790 |
| Leaves | 7.99761 | 7.99751 | 7.99814 |

## F. Resistance To Known And Chosen Plaintext attacks

In proposed method key robustly relies on input image and hash value. Different key values would be created for encrypting different images. It is not possible for an attacker to leak any type of information with a key that was used for other image. So, our method can resist both known plain text and chosen plain text attacks.

## G. Comparisons

A comparison has been made of our proposed method to other algorithms. In terms of some important parameters in table IX. All the comparison has been made by taking Lena image as input. By observing these values, it is said that our proposed method is effective and efficient in many respects.

| Table IX. Comparison of result |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Encryption <br> method | UACI | NPCR | Entropy |  |  |  |
|  |  | Channel <br> $\mathbf{1}$ | Channel <br> $\mathbf{2}$ | Channel <br> $\mathbf{3}$ |  |  |
| Proposed <br> method | 33.47 | 99.61 | 7.9978 | 7.9986 | 7.9988 |  |
| Ref [25] | 33.47 | 99.57 | 7.9927 | 7.9924 | 7.9936 |  |
| Ref [26] | 33.46 | 99.6 | 7.9975 | 7.9980 | 7.9975 |  |
| Ref [27] | 33.43 | 99.54 | 7.9982 | 7.9897 | 7.9885 |  |
| Ref [28] | 33.46 | 99.58 | 7.9967 | 7.981 | 7.9971 |  |

## CONCLUSION

We describe an exclusive colour image encryption with different chaotic functions and dynamic DNA sequences. Different chaotic functions in different stages of our proposed algorithm are applied because chaotic function can generate sensible random sequences which are very effective for image encryption. Traditional cryptographic hash function SHA 256 is used for unique key word generation that make our algorithm resist against different plain text and cipher text attacks. Different important tests have been performed to prove the efficiency of our algorithm. Outcome of these tests proves that the proposed scheme has superior security and high efficacy in image encryption algorithm.
